

Two independent random samples are taken from two populations. Which condition is **necessary** for constructing a confidence interval for  $\mu_1 - \mu_2$ ?

- A. The two samples must be the same size
- B. The populations must have the same mean
- C. The samples must be independent
- D. The population standard deviations must be known

## 🔑 Difference in Sample Means — z vs t (Concise)

Use z (Normal):

- Population standard deviations **known** ( $\sigma_1, \sigma_2$ )
- Normal populations or large samples

Use t (MOST COMMON):

- Population standard deviations **unknown** → use  $s_1, s_2$
  - Normal populations or large samples
- 

## ⚡ Exam Shortcut

👉 Use t unless  $\sigma$  is given

---

## ⚠ Small Samples

If  $n < 30$ :

- No strong skew / no outliers required
- 

## 🧠 One-line takeaway

👉 Unknown  $\sigma$  → t (almost always)

## AP Statistics Decision-Making Exercise

**Instructions:** For each situation, decide whether you should use a **Normal (z) distribution** or a **t distribution**. Give a brief reason.

### Questions

1. A random sample of 50 students is taken. The population standard deviation is known to be 12. You want to estimate the population mean.
2. A random sample of 18 students is taken. The population standard deviation is **unknown**, and the data are approximately normal. You want to test a claim about the population mean.
3. A random sample of 100 adults is taken. The population standard deviation is unknown. The sample standard deviation is 15. You want to construct a confidence interval for the population mean.
4. A population has a known standard deviation of 8. A random sample of 25 observations is taken. You want to test a claim about the population mean.
5. A random sample of 12 students is taken from a strongly skewed population. The population standard deviation is unknown. You want to make an inference about the population mean.
6. Two independent random samples are taken:
  - Group A:  $n = 30$ ,  $s = 10$
  - Group B:  $n = 35$ ,  $s = 12$

The population standard deviations are unknown. You want to compare the two population means.

7. **Challenge:** A random sample of 15 observations comes from a population that is approximately normal. The population standard deviation is unknown. Which distribution should be used, and what additional information would you check before proceeding?

# Stretch and Challenge

## Stretch & Challenge

### Question 1 – How Large Can the Difference Be?

Two independent populations have:

- Population A:  $\mu_A = 80$ ,  $\sigma_A = 12$ ,  $n_A = 36$
- Population B:  $\mu_B = 75$ ,  $\sigma_B = 15$ ,  $n_B = 49$

- Find the mean and standard deviation of the sampling distribution of  $\bar{X}_A - \bar{X}_B$ .
- Find the probability that the difference between the two sample means is **greater than 8**.
- Explain what your answer in part (b) means in context.

---

### Question 2 – Detecting a Difference

The average time students spend completing a mathematics test is 52 minutes at School A and 48 minutes at School B. The population standard deviations are 8 minutes and 10 minutes, respectively.

Independent random samples of 64 students from School A and 100 students from School B are selected.

- Describe the shape, centre, and spread of the sampling distribution of  $\bar{X}_A - \bar{X}_B$ .
- Calculate the probability that  $\bar{X}_A - \bar{X}_B > 6$ .
- The researcher obtains a difference of 6.5 minutes. Explain whether this result would be unusual based on the sampling distribution.

A nutritionist wants to compare the average daily calorie intake of adults in two cities, City A and City B.

- A random sample of 40 adults from City A has a mean of 2,400 calories with a standard deviation of 300 calories.
- A random sample of 35 adults from City B has a mean of 2,300 calories with a standard deviation of 250 calories.

Assume the conditions for inference are satisfied.

**(a)** Define the parameter of interest.

**(b)** State the null and alternative hypotheses to test whether the mean daily calorie intake differs between the two cities.

**(c)** Identify the appropriate test and justify your choice.

**(d)** Calculate the standard error of the difference in sample means.

**(e)** Write the formula for the test statistic (do not calculate the final t-value).

**(f)** Explain the conditions required for using this test.

# Stretch and Challenge

## Stretch & Challenge

### Question 1 – How Large Can the Difference Be?

Two independent populations have:

- Population A:  $\mu_A = 80$ ,  $\sigma_A = 12$ ,  $n_A = 36$
- Population B:  $\mu_B = 75$ ,  $\sigma_B = 15$ ,  $n_B = 49$

- a) Find the mean and standard deviation of the sampling distribution of  $\bar{X}_A - \bar{X}_B$ .
- b) Find the probability that the difference between the two sample means is **greater than 8**.
- c) Explain what your answer in part (b) means in context.

---

### Question 2 – Detecting a Difference

The average time students spend completing a mathematics test is 52 minutes at School A and 48 minutes at School B. The population standard deviations are 8 minutes and 10 minutes, respectively.

Independent random samples of 64 students from School A and 100 students from School B are selected.

- a) Describe the shape, centre, and spread of the sampling distribution of  $\bar{X}_A - \bar{X}_B$ .
- b) Calculate the probability that  $\bar{X}_A - \bar{X}_B > 6$ .
- c) The researcher obtains a difference of 6.5 minutes. Explain whether this result would be unusual based on the sampling distribution.

Table B *t* distribution critical values

| df   | Tail probability <i>p</i> |       |       |       |       |       |       |       |       |       |       |       |

Confidence level *C*

## 🔑 Experimental Design & Causation — Key Points (Concise)

- Only experiments can show causation (只有实验能说明因果关系)
  - Random assignment (随机分配) → balances confounding variables
  - Control group (对照组) → provides comparison
  - Placebo & blinding (安慰剂与盲法) → reduce bias
  - Confounding variables (混杂变量) → must be controlled
  - Well-designed experiment = control + randomization + replication (控制+随机+重复)
  - Observational studies (观察性研究) → show association, NOT causation
  - Large sample size (大样本) → more reliable results
- 

## ⚡ One-line takeaway

👉 Causation requires random assignment and control

A school wants to test whether a new study app improves students' test scores. They select 80 students and allow them to **choose** whether to use the app or not. After one month, students who used the app scored higher on average.

---

### Questions

- (a) Is this an experiment or an observational study? Explain.
- (b) Identify a potential **confounding variable**.
- (c) Can the school conclude that the app **causes** higher scores? Explain.
- (d) Describe how you would redesign the study to allow for a **causal conclusion**.
